

As AI continues to expand across industries, the lack of standardized messaging formats hinders interoperability, governance, and transparency. We propose the creation of an extensible JSON-based AI Messaging Standard, similar to the ACORD standard used in the insurance industry, to define structured electronic exchanges between AI systems, regulatory bodies, and enterprise applications. This standard should be designed with extensibility, allowing organizations to define private extensions to support proprietary or domain-specific AI use cases while maintaining interoperability with the broader ecosystem. Key Areas for Standardization: - AI Model Input Prompts – Standardizing prompt structures ensures consistent model interactions, improving reliability and reducing ambiguity across AI platforms. - AI Model Responses – Establishing a common format for AI-generated outputs allows seamless integration with enterprise applications, regulatory compliance systems, and multi-AI workflows. - AI Model Cards – Providing a standardized format for AI documentation, including model origin, training data sources, performance benchmarks, bias detection, and ethical considerations. - AI Audit Logs – Defining structured records of AI decisions (inputs, outputs, confidence scores) for compliance and risk mitigation purposes. - Explainability and Justifications – Creating a framework for AI-generated explanations, ensuring transparency in high-stakes decision-making (e.g., finance, healthcare, legal). - AI System Performance Metrics – Standardizing reporting for model latency, drift detection, fairness assessments, and operational efficiency. - AI Governance and Compliance – Structuring governance and regulatory compliance reporting in a machine-readable format for auditing and oversight. - Federated AI Learning & Model Sharing – Enabling secure model training and transfer protocols to facilitate collaborative AI development without compromising privacy. - AI Agents and Multi-Agent Coordination – Establishing structured messaging protocols for AI agents to communicate effectively in automated workflows. Extensibility in the AI Messaging Standard: - Organizations should have the ability to extend the standard with private extensions that allow for custom fields, proprietary model metadata, and organization-specific governance rules. - Extensions should be structured in a way that ensures backward compatibility, preventing interoperability issues across different AI platforms. - A governance mechanism should be in place to encourage industry-wide adoption of common extensions, ensuring best practices while allowing innovation. Benefits of an Extensible JSON-Based AI Messaging Standard: - Interoperability – Ensures AI services, platforms, and regulatory bodies can communicate effectively. - Transparency & Trust – Facilitates auditing and oversight of AI decision-making processes. - Efficiency & Scalability – Reduces development and compliance costs by providing a universal messaging framework. - Security & Privacy – Supports encrypted and structured AI data transmission in compliance with regulations. - Customization & Innovation – Provides a structured but flexible framework that allows organizations to tailor AI messaging to their specific needs. Call to Action: We urge policymakers to prioritize the development of this standard, bringing together AI stakeholders, industry leaders, and government agencies to ensure AI systems operate in a structured, secure, and transparent manner while maintaining the flexibility to accommodate evolving AI applications. We appreciate your consideration and look forward to contributing to this initiative.

As AI systems increasingly influence critical areas such as healthcare, transportation, finance, and infrastructure, the requirements for ongoing monitoring of AI systems that impact safety remain unclear. To ensure reliability and public trust, policies and regulations should explicitly

call for continuous automatic monitoring for AI systems where safety is a concern. Key Reasons for Continuous Automatic Monitoring: - AI systems used in safety-critical applications should be monitored in real-time or near-real-time to detect anomalies, failures, or unexpected behaviors that could lead to harm. - Periodic or manual monitoring approaches are insufficient for AI-driven systems that operate dynamically and make real-time decisions. - Automated monitoring can provide continuous oversight, detecting bias, drift, or security vulnerabilities as they arise, rather than after an incident occurs. - Industries such as aviation, autonomous vehicles, and medical AI require rapid response mechanisms that only automated monitoring can support. Clarity Needed in Policy: - Define explicit requirements for continuous monitoring versus periodic audits, ensuring regulatory expectations align with the nature of AI operations. - Establish industry-agnostic guidelines for automated AI monitoring, applicable across sectors where AI impacts human safety. - Require AI developers and operators to implement real-time anomaly detection, logging, and alert mechanisms to ensure rapid intervention when needed. - Provide clear compliance frameworks that specify monitoring expectations for different AI risk levels. Call to Action: We urge policymakers to explicitly address the necessity of continuous automatic monitoring in AI safety regulations to close existing gaps in oversight and ensure AI systems remain safe, reliable, and trustworthy throughout their lifecycle. I appreciate your consideration, please reach out any time to discuss.
