My greatest concern about artificial intelligence is that the artificial intelligence does not show its work. It is nearly impossible to see where the information comes from that arrives at a decision that is given back from artificial intelligence. I have heard that if artificial intelligence doesn't have a reliable source for information that it will make up that source. The only reason science continues to advance is that scientist continue to question the validity of the data that has accumulated in the past. In retirement, we have visited two sites that illustrate the fact that we have lost technology in the past. Machu Picchu and Peru, where if you visit three different guides, you have three different explanations as to how these rocks were shaped and put together. In visiting Egypt, they have not been able to prove how these rocks were put together and moved and quarried. These were technologies that were apparently available to us in the past during times that we had writing and documentation, but these secrets were not recorded and maintained. Artificial intelligence does not allow questioning from where the information comes. I have a retired physician, and unfortunately, my colleagues have become more students than colleagues. When I started in practice over 40 years ago, we had journal clubs that would critically evaluate articles to determine whether the information presented was actually true and useful. We now sit in lectures and have experts reading from slides that we diligently watch in an audience and do not question. This does not advance science. We have lost significant trust from our patient by not critically, examine the information that we are presented.
