Eric Doherty

As one who covers multi entities in the IT world, the need for certain guidelines for AI is needed. Cybersecurity needs Patient record privacy needs Access and network privacy needs On the cybersecurity front, the need for no less than multi-factor access and identity within the AI access points is needed. If using AI on platforms or in data manipulation, the need for MF in any AI environment is necessary. Single and two-factor is not enough and bad AI actors can easily compromise systems. The need for patient health information privacy, like HIPAA, of patients health is a key need. With AI this can be enhanced but can also lead to easy access of those records. The need for strict guidelines on how access is granted and who has access to the information is needed. What areas are open and what areas that are closed within systems, to certain access is needed. On the AI front, IT platforms that use AI and are dealing with patient health records should have systems in place to protect that information. No matter what. The ability to delete any and all information once it is used should be apparent. This will enhance the privacy of said information. There also needs to be AI rules and regulations that are fully documented and vetted in this space. On the access and network privacy needs, this goes back to my earlier commentary. Who has access? What do they have access to? What is being done with the data and being used? All questions that need documentation on how it is being used and provided to others. In the realm of AI, access to the data is key. There needs to be robust guidelines that not only provide the proper directions on how the data is to be used but also has limitations on how that data can be used and where the lines of privacy are delegated. My main concern is that if guidelines are not put into place, the ability to "run rogue" is problematic. Last year, the United Health Care/United Healthcare Breach provided access to millions of patient records and cost the health system, and the US population, billions of dollars. That figure has still not been figured out. \$50B? \$100B? More? If no guidelines are put into place the potential of this threat happening again through the use of AI, and having windows of opportunities within IT systems wide open and accessible, provides ample ability to easily gain access to this information.
