James Quinn

As an AI practitioner for a large technology company, I strongly urge that the new AI Action Plan prioritize reducing non-renewable energy consumption and increasing efficiency. This is not just a policy action; it is a necessity for human beings' future. In my role, I see firsthand how AI can drive innovation and efficiency. However, the energy demands of AI are significant and growing. This directly impacts my workplace and community, as we strive to balance technological advancement with clean air and water (which gas, oil, and coal-based energy actively harm). To address this, I propose that we remove all barriers to a rapid buildout of solar and wind power. Supporting this proposal, research from the International Energy Agency indicates that data centers currently account for about 1% of global electricity demand, a figure that could rise significantly without intervention. Transitioning to renewable energy and improving efficiency can mitigate this impact. I encourage my fellow tech workers and AI advocates to join me in this call to action.
