Mike Jeub

AI involves "norms" and the use of such norms needs to be apparent in all the "decisions". The basic idea is that a linear norm is less than a 2 norm or surface or areal norm, and a multiple norm above the 2 norm is greater than the two norm. We can see how manipulating norms affects the strength and usefulness of the decisioning. Each kind of norm needs to be exposed as to the problems decided upon, and this depends also on the number of layers and amounts of backpropagation. I think that manipulators and slick salesmen need to stay out of this business. After all, these are just search engines that are better than page rank, and we all need this unfettered and unregulated. Nobody is going to be able to abuse anything any more than we have already suffered up to this point. Congress are the worst people to do anything with AI, they do not know s&^% and talk bulls&^% to the people. My concern is that the inequalities of norms can be an easy way to disable the true functionality of great decisions in deductive LLMs and other neural networking applications. We need full access to the architecture of certain things so that AI becomes a great tool rather than another control module for the NSA/CIA/deep state &^%birds like Palantir etc. We need to be naturally free to develop and especially understand the frameworks rather than the "quantum computing" idiocy of congress. What decisioning aspects are matters because of the nature of hypersurfaces interleaving the decisioning directions. One needs only to look at the AP style manual as an example of poor renderings in the LLM depths. My main point is that the decisioning basis should never be secretive or hidden to users of the technology. A group on decisioning "norms" would be a useful subcategorical thing to have standards upon, whereby AI itself could start to round it out in ways that could make systems quite robust and more trustworthy.
