Seth Roseman

I am writing to ask the White House to prioritize reducing energy consumption and increasing efficiency in the new AI Action Plan. As AI technologies continue to become more integrated into our lives, it is crucial that we address the significant energy demands and associated carbon emissions of these systems. The AI Action Plan should emphasize energy efficiency as a top policy action. This includes investing in research and development to create more energy-efficient AI algorithms and hardware. By focusing on efficiency, we can reduce the overall energy consumption of AI systems without compromising their performance. Data centers, which power much of the AI infrastructure, should be encouraged to transition to renewable energy sources such as solar and wind. This transition is essential for mitigating the carbon emissions associated with AI's energy consumption. There should be a clear, definitive timeline to achieve net-zero emissions for AI operations. Data centers and AI developers should likewise adopt best practices for energy efficiency, including optimizing cooling systems, using energy-efficient hardware, and implementing AI algorithms that require less computational power. These practices can significantly reduce the energy footprint of AI operations. According to a study by the University of Massachusetts Amherst, training a large AI model can emit as much carbon as five cars in their lifetimes. This highlights the urgent need to address AI's energy consumption. The International Energy Agency reports that data centers consume about 1% of global electricity demand, and this is expected to rise with the increasing use of AI. Transitioning to renewable energy can help offset this growing demand. Companies like Google and Microsoft have already committed to achieving carbon-neutral data centers, demonstrating that this goal is both feasible and beneficial for the environment. As a resident of York, Pennsylvania, I am particularly concerned about how AI's energy use may impact our local environment and economy. The restart of Three Mile Island to power AI has many who lived through its meltdown in 1979 worried. By prioritizing energy efficiency and the transition to renewable energy, the AI Action Plan can create a sustainable future for AI technologies and help protect communities like ours from the adverse effects of climate change of (another) nuclear meltdown. By prioritizing energy efficiency and the transition to renewable energy, the AI Action Plan can lead the way in creating a sustainable future for AI technologies. Again, I ask the White House to incorporate these recommendations into the new AI Action Plan to ensure that AI development aligns with our climate goals.
