

Shayne Nelson

The US Government should do the following: 1. Invest in Quantum computing. This is the next step in speed and machine learning, graduating from the standard 0/1 computer language to an expanded set of unlimited resources for computers 2. Invest equally in Quantum security. Companies such as Sealsqcorp (LAES) have pivoted semi conductor manufacturing to creating security solutions for Quantum computing 3. Standardize LLM instruction guidelines to limit the ability for machine learning to exceed human constraints. 4. Invest in US AI startups, provide funds to smaller companies to engineer lower cost increased security applications 5. Enforce standard release QA processes across the industry to reduce critical and zero day vulnerabilities. Breaches occur because of the lack of attention to detail. The highest most evident attack vector to AI is through vulnerabilities, or security holes not found in initial QA. This is because many small, medium and enterprise companies do not enforce release management and vulnerability patching cycles that will reduce the overall risk of unauthorized access to active source code, footholds in AI networks and the compromise of sensitive data 6. Require the security enforcement of LLMs and the type of information that is fed to and stored in LLMs to prevent the compromise of sensitive information.
